Keywords:
Low-rank tensor recovery (LRTR)
Mode-$k_1k_2$ tensor unfolding
Tensor $N$-tubal rank
Weighted sum of tensor nuclear norm (WSTNN)
Alternating direction method of multipliers (ADMM)

A B S T R A C T

The recent popular tensor tubal rank, defined based on tensor singular value decomposition (t-SVD), yields promising results. However, its framework is applicable only to three-way tensors and lacks the flexibility necessary to handle different correlations along different modes. To tackle these two issues, we define a new tensor unfolding operator, named mode-$k_1k_2$ tensor unfolding, as the process of lexicographically stacking all mode-$k_1k_2$ slices of an $N$-way tensor into a three-way tensor, which is a three-way extension of the well-known mode-$k$ tensor matricization. On this basis, we define a novel tensor rank, named the tensor $N$-tubal rank, as a vector consisting of the tubal ranks of all mode-$k_1k_2$ unfolding tensors, to depict the correlations along different modes. To efficiently minimize the proposed $N$-tubal rank, we establish its convex relaxation: the weighted sum of the tensor nuclear norm (WSTNN). Then, we apply the WSTNN to low-rank tensor completion (LRTC) and tensor robust principal component analysis (TRPCA). The corresponding WSTNN-based LRTC and TRPCA models are proposed, and two efficient alternating direction method of multipliers (ADMM)-based algorithms are developed to solve the proposed models. Numerical experiments demonstrate that the proposed models significantly outperform the compared ones.

1. Introduction

As a multidimensional array, the tensor [20] plays an increasingly significant role in many applications, such as color image/video processing [13,26,32,45], hyperspectral/multispectral image (HSI/MSI) processing [7,22,47,38], background subtraction [18,3], video rain streak removal [34,21], and magnetic resonance imaging (MRI) data recovery [15,17,37,6]. Many of these applications can be formulated as a class of tensor recovery problems, i.e., recovering an underlying tensor from its corrupted observation. Particularly, as two typical examples, tensor completion aims to complete missing elements, and tensor robust principal component analysis (TRPCA) aims to remove sparse outliers. The key to tensor recovery is to explore the redundancy prior of the underlying tensor, which is usually formulated as low-rankness. Thus, low-rank modeling has been widely studied and has achieved great success in the tensor recovery task.
The traditional matrix recovery is a two-way tensor recovery problem. Since the matrix rank, measured by the number of non-zero singular values, is powerful enough to capture the global information of a matrix, most matrix recovery methods aim to minimize the matrix rank \([2, 30, 5]\). However, directly minimizing the matrix rank is NP-hard \([11]\). To tackle this issue, the nuclear norm \(\| \cdot \|_2\), i.e., the sum of all non-zero singular values, has been proposed to approximate the matrix rank, leading to great successes \([2, 1]\).

Tensor recovery can be viewed as an extension of matrix recovery. Inspired by the success of matrix rank minimization, it seems natural to recover the underlying tensor by minimizing the tensor rank. Mathematically, a general low-rank tensor recovery (LRTC) model can be written as

\[
\min_{\mathcal{X}} \text{rank}(\mathcal{X}) + \lambda L(\mathcal{X}, \mathcal{F}),
\]

where \(\mathcal{X}\) is the underlying tensor, \(\mathcal{F}\) is the observed tensor, and \(L(\mathcal{X}, \mathcal{F})\) is the loss function between \(\mathcal{X}\) and \(\mathcal{F}\), e.g., \(X_0 = \mathcal{F}_0\) for low-rank tensor completion (LRTC) and \(\| F - X \|\) for TRPCA. A conclusive issue of LRTC is the definition of the tensor rank. However, unlike the matrix rank, the definition of the tensor rank is not unique. Many research efforts have been devoted to defining the tensor rank, and most of them are defined based on the corresponding tensor decomposition, such as the CANDECOMP/PARAFAC (CP) rank based on CP decomposition \([4, 44]\), the Tucker rank based on Tucker decomposition \([8, 24, 23, 46]\), and the tensor tubal rank based on tensor singular value decomposition (t-SVD) \([19, 14, 43]\).

The CP rank and the Tucker rank are the two most typical definitions of the tensor rank. The CP rank is defined as the minimum number of rank-one tensors required to express a tensor \([20]\), i.e.,

\[
\text{rank}_{cp}(\mathcal{X}) := \min \left\{ r | \mathcal{X} = \sum_{i=1}^{r} a_i \otimes a_i \otimes a_i, a_i \in \mathbb{R}^n \right\},
\]

where \(\mathcal{X}\) is an \(N\)-way tensor and \(\otimes\) denotes the vector outer product. Although the measure of the CP rank is consistent with that of the matrix rank, it is difficult to establish a solvable relaxation form. The Tucker rank is defined as a vector, the \(k\)-th element of which is defined as the rank of the mode-\(k\) unfolding matrix \([20]\), i.e.,

\[
\text{rank}_{t}(\mathcal{X}) := (\text{rank}(X_{(1)}), \text{rank}(X_{(2)}), \ldots, \text{rank}(X_{(n)})),
\]

where \(\mathcal{X}\) is an \(N\)-way tensor and \(X_{(k)}(k = 1, 2, \ldots, N)\) is the mode-\(k\) unfolding of \(\mathcal{X}\). To efficiently minimize the Tucker rank, Liu et al. \([24]\) considered its convex relaxation, defined as the sum of the nuclear norm (SNN) of unfolding matrices, i.e.,

\[
\text{rank}_{kX}(\mathcal{X}) := \sum_{k=1}^{N} z_k \| X_{(k)} \|_2,
\]

where \(z_k \geq 0 (k = 1, 2, \ldots, N)\) and \(\sum_{k=1}^{N} z_k = 1\). Based on the SNN, Liu et al. \([24]\) established an LRTC model with three solving algorithms (SiLRTC, FaLRTC, and HaLRTC), and Goldfarb and Qin \([9]\) proposed a TRPCA model. Although the SNN can flexibly exploit the correlations along different modes by adjusting the weights \(z_k\) \([29]\), as noted in \([19, 35]\), when a tensor is unfolded to a matrix along one mode, the structure information along other modes is inevitably destroyed. Thus, the SNN faces difficulty in preserving the intrinsic structure of the tensor. Moreover, Mu et al. \([28]\) showed that the SNN based on standard mode-\(k\) unfolding is substantially suboptimal and subsequently offered a generalized tensor unfolding to unfold an \(N\)-way tensor to a more balanced (square) matrix, leading to promising results.

Recently, the tensor tubal rank and multi-rank, based on t-SVD, have received considerable attention \([19, 43, 14, 16, 12, 48, 25, 36, 31]\). As a generalization of the matrix singular value decomposition (SVD), t-SVD regards a three-way tensor \(\mathcal{X}\) as a matrix, each element of which is a tube (mode-3 fiber), and then decomposes \(\mathcal{X}\) as

\[
\mathcal{X} = \mathcal{U} * \mathcal{S} * \mathcal{V}^T,
\]

where \(\mathcal{U}\) and \(\mathcal{V}\) are orthogonal tensors, \(\mathcal{S}\) is an \(f\)-diagonal tensor, \(\mathcal{V}^T\) denotes the conjugate transpose of \(\mathcal{V}\), and \(*\) denotes the t-product (see details in Section 2). Mathematically, this decomposition is equivalent to a series of matrix SVDs in the Fourier domain \([43]\), i.e.,

\[
\mathcal{X}^{(i)} = \mathcal{U}^{(i)} \mathcal{S}^{(i)} (\mathcal{V}^{(i)})^T, \quad i = 1, 2, \ldots, n_3,
\]

where \(\mathcal{X}^{(i)}\) is the \(i\)-th frontal slice of \(\mathcal{X}\). \(\mathcal{X}\) is generated by performing the discrete Fourier transformation (DFT) along each tube of \(\mathcal{X}\). The multi-rank of \(\mathcal{X}\) is defined as a vector whose \(i\)-th element is the rank of \(\mathcal{X}^{(i)}\), i.e.,

\[
\text{rank}_{m}(\mathcal{X}) := (\text{rank}(\mathcal{X}^{(1)}), \text{rank}(\mathcal{X}^{(2)}), \ldots, \text{rank}(\mathcal{X}^{(n_3)})).
\]

The tubal rank of \(\mathcal{X}\) is defined as the number of non-zero tubes of \(\mathcal{S}\), i.e.,

\[
\text{rank}(\mathcal{X}) := \# \{ i : \mathcal{S}(i, i, :) \neq 0 \}.
\]

Specifically, the tensor tubal rank is equal to the maximum value of the tensor multi-rank. Since directly minimizing the tensor tubal/multi-rank is NP-hard \([11]\), Semerci et al. \([31]\) developed the tensor nuclear norm (TNN) as their convex surrogate, i.e.,
\[ \| \mathcal{X} \|_{\text{TNN}} := \sum_{i=1}^{n_3} |X_i| . \]

Then, Zhang et al. [43] proposed the TNN-based LRTC model, Lu et al. [25] further proved the exactly-recover-property for the TNN-based TRPCA model, and Hu et al. [12] proposed a twist tensor nuclear norm (t-TNN) for video completion.

Although the TNN has shown its effectiveness in preserving the intrinsic structure of a tensor [43,12], it has two obvious shortcomings. One is that it cannot be applied to N-way tensors (N > 3). The other is that it lacks the flexibility necessary to address different correlations along different modes, especially the third mode. Specifically, under the framework of t-SVD, for a three-way tensor, the correlations along the first and second modes are characterized by matrix SVD, while that along the third mode is encoded by an embedded circular convolution [43,25]. However, most real-world data always have different correlations along different modes, e.g., the correlation of an HSI along its spatial mode should be much stronger than that along its spectral mode. Thus, treating each mode flexibly similar to the SNN is expected to compensate for this defect.

To apply t-SVD to N-way tensors (N > 3), in this paper, we define a three-way extension of the tensor matricization operator, named mode-$k_1 k_2$ tensor unfolding ($k_1 < k_2$), as the process of lexicographically stacking the mode-$k_1 k_2$ slices of an N-way tensor \( \mathcal{X} \in \mathbb{R}^{n_1 \times n_2 \times \cdots \times n_N} \) into the frontal slices of a three-way tensor \( \mathcal{X}_{k_1 k_2} \in \mathbb{R}^{n_1 \times n_2 \times 1 \times \cdots \times 1} \) (see details in Section 3).

Table 1 compares the Tucker rank and the N-tubal rank of two HSIs. As observed, the Tucker rank suggests a strong correlation along the third mode. According to the tensor N-tubal rank, this strong correlation is inadequately depicted by the first element (the tubal rank), while it can be exactly depicted by the other two elements. This observation demonstrates that compared with the tensor tubal rank, the proposed tensor N-tubal rank achieves a more flexible depiction for the correlations along different modes.

To efficiently minimize the proposed tensor N-tubal rank, we establish its convex relaxation: the weighted sum of the tensor nuclear norm (WSTNN), which can be expressed as the weighted sum of the TNN of each mode-$k_1 k_2$ unfolding tensor, i.e.,

\[ \| \mathcal{X} \|_{\text{WSTNN}} := \sum_{1 \leq k_1 < k_2 \leq N} \alpha_{k_1 k_2} \| X_{k_1 k_2} \|_{\text{TNN}} , \]

where \( \alpha_{k_1 k_2} \geq 0 (1 \leq k_1 < k_2 \leq N, k_1, k_2 \in \mathbb{Z}) \) and \( \sum_{1 \leq k_1 < k_2 \leq N} \alpha_{k_1 k_2} = 1 \). Then, we apply the WSTNN to two typical LRTR problems, i.e., LRTC and TRPCA, and propose the corresponding WSTNN-based models. Meanwhile, two efficient alternating direction method of multipliers (ADMM)-based algorithms are developed to solve the proposed models. Numerous numerical experiments on synthetic and real-world data are conducted to illustrate the effectiveness and efficiency of the proposed methods.

The rest of this paper is organized as follows. Section 2 presents some preliminary knowledge. Section 3 gives the definitions of the tensor N-tubal rank and its convex surrogate WSTNN. Section 4 proposes the WSTNN-based LRTC and TRPCA models and develops two efficient ADMM-based solvers. Section 5 evaluates the performance of the proposed models and compares the results with those of state-of-the-art competing methods. Section 6 concludes this paper.

2. Notations and preliminaries

In this section, we give some basic notations and briefly introduce some definitions used throughout the paper [20,43].

We denote vectors as bold lowercase letters (e.g., \( \mathbf{x} \)), matrices as uppercase letters (e.g., \( \mathbf{X} \)), and tensors as calligraphic letters (e.g., \( \mathcal{X} \)). Taking a three-way tensor \( \mathcal{X} \in \mathbb{R}^{n_1 \times n_2 \times \cdots \times n_N} \) as an example, we denote its \((i, j, s)\)-th element as \( \mathcal{X}(i, j, s) \) or \( X_{ij3} \) and its \((i, j)\)-th mode-1, mode-2, and mode-3 fibers as \( \mathcal{X}(i, :, j, :) \), \( \mathcal{X}(i, :, :, j) \), and \( \mathcal{X}(i, :, :, :) \), respectively. We use \( \mathcal{X}(i, :, :, :) \) to denote the \( i \)-th horizontal, lateral, and frontal slices of \( \mathcal{X} \), respectively. More compactly, \( X_0 \) is short for \( \mathcal{X}(\cdot, :, :) \). The Frobenius norm of \( \mathcal{X} \) is defined as \( \| \mathcal{X} \|_F := \left( \sum_{i,j,s} |X(i,j,s)|^2 \right)^{1/2} \). The \( \ell_1 \) norm of \( \mathcal{X} \) is defined as \( \| \mathcal{X} \|_1 := \sum_{i,j,s} |X(i,j,s)| \). We use \( \vec{\mathcal{X}} \) to denote the tensor generated by performing DFT along each tube of \( \mathcal{X} \), i.e., \( \vec{\mathcal{X}} = \vec{\mathcal{F}}(\mathcal{X}, \cdot, :) \). Naturally, we can compute \( \mathcal{X} \) via \( \mathcal{X} = \vec{\mathcal{F}}^{-1}(\vec{\mathcal{X}}, \cdot, :) \).

The vectorization of an N-way tensor \( \mathcal{X} \in \mathbb{R}^{n_1 \times n_2 \times \cdots \times n_N} \) is denoted as \( \text{vec}(\mathcal{X}) \in \mathbb{R}^{n_1 n_2 \cdots n_N} \), is defined as \( \text{vec}(\mathcal{X}) = \mathbf{x}(i_1, i_2, \ldots, i_N) \) with \( i_j = i_l + \sum_{j=1}^{N-1} ((i_l - 1) \prod_{m=1}^{j-1} n_m) \).

1 The rank is approximated by the numbers of singular values larger than 1% of the largest ones.
The mode-\(k\) tensor matricization of an \(N\)-way tensor \(X \in \mathbb{R}^{n_1 \times n_2 \times \cdots \times n_N}\) is denoted as \(X(k) \in \mathbb{R}^{\prod_{i=1}^N n_i}\), the \((i, j)\)-th element of which maps to the \((i_1, i_2, \ldots, i_N)\)-th element of \(X\), where

\[ j = 1 + \sum_{s=1, s \neq k}^N (i_s - 1) n_s + \prod_{m=1, m \neq k}^{s-1} n_m. \]

The corresponding operator and inverse operator are denoted as “unfold” and “fold”, respectively, i.e., \(X(k) = \text{unfold}(X, k)\) and \(X = \text{fold}(X(k), k)\).

For a three-way tensor \(X \in \mathbb{R}^{n_1 \times n_2 \times n_3}\), the block circulation operation is defined as

\[ \text{bcirc}(X) := \begin{pmatrix} X^{(1)} & X^{(n_1)} & \cdots & X^{(2)} \\ X^{(2)} & X^{(1)} & \cdots & X^{(3)} \\ \vdots & \vdots & \ddots & \vdots \\ X^{(n_1)} & X^{(n_1-1)} & \cdots & X^{(1)} \end{pmatrix} \in \mathbb{R}^{n_1 \times n_2 \times n_3}. \]

The block diagonalization operation and its inverse operation are defined as

\[ \text{bdiag}(X) := \begin{pmatrix} X^{(1)} \\ X^{(2)} \\ \vdots \\ X^{(n_1)} \end{pmatrix} \in \mathbb{R}^{n_1 \times n_2 \times n_3}, \quad \text{bdfold}(\text{bdiag}(X)) := X. \]

The block vectorization operation and its inverse operation are defined as

\[ \text{bvec}(X) := \begin{pmatrix} X^{(1)} \\ X^{(2)} \\ \vdots \\ X^{(n_1)} \end{pmatrix} \in \mathbb{R}^{n_1 \times n_2}, \quad \text{bvfold}(\text{bvec}(X)) := X. \]

**Definition 1** (t-product). The t-product between two three-way tensors \(X \in \mathbb{R}^{n_1 \times n_2 \times n_3}\) and \(Y \in \mathbb{R}^{n_2 \times n_3 \times n_1}\) is defined as

\[ X \ast Y := \text{bvfold}(\text{bcirc}(X) \text{bvec}(Y)) \in \mathbb{R}^{n_1 \times n_2 \times n_3}. \]

Indeed, the t-product can be regarded as a matrix–matrix multiplication, except that the multiplication operation between scalars is replaced by circular convolution between the tubes, i.e.,

\[ F = X \ast Y \iff F(i, j, :) = \sum_{s=1}^{n_2} X(i, s, :) \circ Y(t, j, :), \]

where \(\circ\) denotes the circular convolution between two tubes. Since that circular convolution in the spatial domain is equivalent to multiplication in the Fourier domain, the t-product between two tensors \(F = X \ast Y\) is equivalent to

\[ F = \text{bdfold}(\text{bdiag}(X) \text{bdiag}(Y)). \]

**Definition 2** (special tensors). The conjugate transpose of a three-way tensor \(X \in \mathbb{R}^{n_1 \times n_2 \times n_3}\), denoted as \(X^T\), is the tensor obtained by conjugate transposing each of the frontal slices and then reversing the order of transposed frontal slices 2 through \(n_3\). The identity tensor \(I \in \mathbb{R}^{n_1 \times n_2 \times n_3}\) is a tensor whose first frontal slice is the identity matrix, and other frontal slices are all zeros. A three-way tensor \(Q\) is orthogonal if \(Q \ast Q^T = Q^T \ast Q = I\). A three-way tensor \(S\) is f-diagonal if each of its frontal slices is a diagonal matrix.

Table 1
The rank estimation of two HSI.
Theorem 1 (t-SVD). Let $X \in \mathbb{R}^{n_1 \times n_2 \times n_3}$ be a three-way tensor, then it can be factored as

$$X = U /C3 S /C3 V^T,$$

where $U \in \mathbb{R}^{n_1 /C2 n_2 /C2 n_3}$ and $V \in \mathbb{R}^{n_2 /C2 n_2 /C2 n_3}$ are orthogonal tensors, and $S \in \mathbb{R}^{n_1 /C2 n_2 /C2 n_3}$ is an f-diagonal tensor.

Algorithm 1 The t-SVD for three-way tensors

Input $X \in \mathbb{R}^{n_1 \times n_2 \times n_3}$.

1: $\hat{X} \leftarrow \text{fft}(X, [1, 3]).$
2: for $i = 1$ to $n_3$ do
3: $[U, S, V] = \text{svd}(\hat{X}^{(i)}).$
4: $U^{(i)} \leftarrow U, S^{(i)} \leftarrow S, V^{(i)} \leftarrow V.$
5: endfor
6: $\hat{U} \leftarrow \text{ifft}(\hat{U}, [1, 3]).$
7: $S \leftarrow \text{ifft}(S, [1, 3]).$
8: $V \leftarrow \text{ifft}(V, [1, 3]).$

Output: $U, S, V.$

The t-SVD scheme is illustrated in Fig. 1, and its computation is given in Algorithm 1. Now, we give the definitions of the tensor multi-rank and tubal rank.

Definition 3 (tensor multi-rank and tubal rank). Let $X \in \mathbb{R}^{n_1 \times n_2 \times n_3}$ be a three-way tensor. The tensor multi-rank of $X$ is a vector $\text{rank}_m(X) \in \mathbb{R}^{n_3}$, the $i$-th element of which is the rank of the $i$-th frontal slice of $X$, where $X = \text{fft}(X, [1, 3])$. The tubal rank of $X$, denoted as $\text{rank}_t(X)$, is defined as the number of non-zero tubes of $S$, where $S$ comes from the t-SVD of $X : X = U + S + VT$. That is, $\text{rank}_t(X) = \max(\text{rank}_m(X)).$

Definition 4 (tensor nuclear norm (TNN)). The tensor nuclear norm of a tensor $X \in \mathbb{R}^{n_1 \times n_2 \times n_3}$, denoted as $\|X\|_{\text{TNN}}$, is defined as the sum of the singular values of all the frontal slices of $X$, i.e.,

$$\|X\|_{\text{TNN}} := \sum_{i=1}^{n_3} \|X^{(i)}\|_2,$$

where $X^{(i)}$ is the $i$-th frontal slice of $X$, with $X = \text{fft}(X, [1, 3]).$

3. Tensor $N$-tubal rank and convex relaxation

In this section, we first propose the mode-$k_1 k_2$ tensor unfolding operation and then give the definitions of the tensor $N$-tubal rank and its convex relaxation WSTNN.

As noted in Section 1, the framework of t-SVD and the corresponding tubal rank apply only to three-way tensors and lack the flexibility to handle different correlations along different modes. To address these two issues, we define a novel tensor unfolding operation to transform an $N$-way tensor into a three-way tensor by reordering its slices along any two modes.

Definition 5 (mode-$k_1 k_2$ slices). For an $N$-way tensor $X \in \mathbb{R}^{n_1 \times n_2 \times \cdots \times n_N}$, its mode-$k_1 k_2$ slices ($X^{k_1 k_2}$, $1 \leq k_1 < k_2 \leq N, k_1, k_2 \in \mathbb{Z}$) are two-dimensional sections, defined by fixing all but the mode-$k_1$ and the mode-$k_2$ indexes.
Definition 6 (mode-$k_1k_2$ tensor unfolding). For an $N$-way tensor $\mathbf{X} \in \mathbb{R}^{n_1 \times n_2 \times \cdots \times n_N}$, its mode-$k_1k_2$ unfolding is a three-way tensor denoted by $\mathbf{X}_{(k_1k_2)} \in \mathbb{R}^{n_{k_1} \times n_{k_2} \times \prod_{k \neq k_1k_2} n_k}$, the frontal slices of which are the lexicographic orderings of the mode-$k_1k_2$ slices of $\mathbf{X}$. Mathematically, the $(i_1,i_2,\ldots,i_N)$-th element of $\mathbf{X}$ maps to the $(i_{k_1}i_{k_2}j)$-th element of $\mathbf{X}_{(k_1k_2)}$, where

$$ j = 1 + \sum_{k=1}^{N} (i_k-1)f_k \text{ with } f_k = \prod_{m=1\atop m \neq k}^{N} n_m. $$

We define the corresponding operation as $\mathbf{X}_{(k_1k_2)} := t-$unfold$(\mathbf{X},k_1,k_2)$ and its inverse operation as $\mathbf{X} := t-$fold$(\mathbf{X}_{(k_1k_2)},k_1,k_2)$. Examples of Definition 5 and Definition 6 can be found in the Appendix. Specifically, for a three-way tensor, the proposed tensor unfolding operation does not involve dimensional reduction but corresponds to a permutation operation, i.e.,

$$ \mathbf{X}(i,j,s) = \mathbf{X}_{(12)}(i,j,s) = \mathbf{X}_{(13)}(i,s,j) = \mathbf{X}_{(23)}(j,s,i). $$

Therefore, in this case, we use $\text{permute}$ and $\text{ipermute}$ to replace $t-$unfold and $t-$fold, respectively.

By performing t-SVD on each mode-$k_1k_2$ unfolding tensor, we propose a novel tensor rank, named the tensor $N$-tubal rank.

Definition 7 ($N$-tubal rank). The tubal rank of an $N$-way tensor $\mathbf{X} \in \mathbb{R}^{n_1 \times n_2 \times \cdots \times n_N}$ is defined as a vector, the elements of which contain the tubal rank of all mode-$k_1k_2$ unfolding tensors, i.e.,

$$ N - \text{rank}_t(\mathbf{X}) = (\text{rank}_t(\mathbf{X}_{(12)}), \text{rank}_t(\mathbf{X}_{(13)}), \ldots, \text{rank}_t(\mathbf{X}_{(1N)}), \text{rank}_t(\mathbf{X}_{(23)}), \ldots, \text{rank}_t(\mathbf{X}_{(2N)}), \ldots, \text{rank}_t(\mathbf{X}_{(N-1N)})) \in \mathbb{R}^{N(N-1)/2}. $$

Clearly, for a three-way tensor, the tensor tubal rank is the first element of the tensor $N$-tubal rank. By taking the HSI Washington DC Mall shown in Fig. 2 as an example, its low $N$-tubal rank prior can be observed both quantitatively and visually. Specifically, the proposed $N$-tubal rank combines the advantages of the Tucker rank and tubal rank. On the one hand, compared with the mode-$k_1$ unfolding matrix, the mode-$k_1k_2$ unfolding tensor avoids the destruction of the structure information along the $k_2$-th mode. On the other hand, as shown in Fig. 2, the tubal rank of each mode-$k_1k_2$ unfolding (permutation) tensor $\mathbf{X}_{(k_1k_2)}$ more directly depicts the correlation of the $k_1$-th and the $k_2$-th modes, i.e., it lacks direct characterization of the correlation along other modes. Because all mode-$k_1k_2$ unfolding tensors are considered simultaneously, the proposed $N$-tubal rank can effectively exploit the correlations along all modes. The following theorem reveals the relationship between the tensor $N$-tubal rank and Tucker rank.

Theorem 2 ($N$-tubal rank and Tucker rank). Let $\mathbf{X} \in \mathbb{R}^{n_1 \times n_2 \times \cdots \times n_N}$ be an $N$-way tensor with Tucker rank $(r_1, r_2, \ldots, r_N)$ and Tucker decomposition

$$ \mathbf{X} = \mathbf{G} \times_1 \mathbf{A}_1 \times_2 \mathbf{A}_2 \times_3 \cdots \times_N \mathbf{A}_N = \sum_{i_1=1}^{r_1} \cdots \sum_{i_N=1}^{r_N} \mathbf{G}(i_1, i_2, \ldots, i_N) \mathbf{a}_{i_1} \circ \mathbf{a}_{i_2} \circ \cdots \circ \mathbf{a}_{i_N}. $$

(b) The mode-$k_1k_2$ permutation tensors of $\mathbf{X}$. (c) The tensors $\mathbf{X}_{(k_1k_2)}$ generated by performing a DFT along each tube of $\mathbf{X}_{(k_1k_2)}$. (d) Singular value curves from the second to the end frontal slices of $\mathbf{X}_{(k_1k_2)}$. (e) Singular value curves of the first frontal slices of $\mathbf{X}_{(k_1k_2)}$. 
where $G \in \mathbb{R}^{n_1 \times n_2 \times \cdots \times n_T}, A_k \in \mathbb{R}^{n_k \times n_T}$ ($k = 1, 2, \ldots, N$), and $a_k^i$ is the $i$-th column of $A_k$. Then, each element of the $N$-tubal rank is bounded by the Tucker rank along the corresponding modes, i.e.,

$$\text{tubal} - \text{Rank}({X_{(k_1, k_2)}}) \leq \min \{r_{k_1}, r_{k_2}\}.$$ 

This theorem demonstrates theoretically that the proposed $N$-tubal rank learns the global correlations within multi-dimensional data as the Tucker rank does. Furthermore, we reveal the relationship between the tensor $N$-tubal rank and CP rank in the next theorem.

**Theorem 3 (N-tubal rank and CP rank).** Assume that the CP rank of an $N$-way tensor $X \in \mathbb{R}^{n_1 \times n_2 \times \cdots \times n_N}$ is $r$ and that its CP decomposition is

$$X = \sum_{i=1}^{r} a_i^1 \circ a_i^2 \circ \cdots \circ a_i^N, a_i^k \in \mathbb{R}^{n_k}, k = 1, 2, \ldots, N.$$ 

Then, the $N$-tubal rank of $X$ is at most $r \times \text{ones}(N(N - 1)/2, 1)$. Specifically, we define vector sets

$$\mathbb{V}_1 = \{a_i^1 | i = 1, 2, \ldots, r\},$$

$$\mathbb{V}_2 = \{a_i^2 | i = 1, 2, \ldots, r\},$$

$$\vdots$$

$$\mathbb{V}_N = \{a_i^N | i = 1, 2, \ldots, r\},$$

and

$$c_i = \text{vec}(c_i) \in \mathbb{R}^{n_1 \times n_2 \times \cdots \times n_N}, i = 1, 2, \ldots, r,$$

where $c_i = a_i^1 \circ a_i^2 \circ \cdots \circ a_i^{k_i-1} \circ a_i^{k_i+1} \circ \cdots \circ a_i^{k_i-1} \circ a_i^{k_i+1} \circ \cdots \circ a_i^N$. If each vector set $\mathbb{V}_i$ is linearly independent and there is a $j$ such that each $j$-th element of $c_i$ is non-zero, the $N$-tubal rank is equal to $r \times \text{ones}(N(N - 1)/2, 1)$.

Detailed proofs of Theorem 2 and Theorem 3 can be found in the Appendix. To effectively minimize the tensor $N$-tubal rank, we propose the following WSTNN as its convex relaxation.

**Definition 8 (weighted sum of the tensor nuclear norm).** The WSTNN of an $N$-way tensor $X \in \mathbb{R}^{n_1 \times n_2 \times \cdots \times n_N}$, denoted as $\|X\|_{\text{WSTNN}}$, is defined as the weighted sum of the TN of each mode-$k, k_2$ unfolding tensor, i.e.,

$$\|X\|_{\text{WSTNN}} := \sum_{1 \leq k_1 < k_2 \leq N} z_{k_1 k_2} \|X_{(k_1, k_2)}\|_{\text{TNN}}.$$ 

where $z_{k_1 k_2} \geq 0 (1 \leq k_1 < k_2 \leq N, k_1, k_2 \in \mathbb{Z})$ and $\sum_{1 \leq k_1 < k_2 \leq N} z_{k_1 k_2} = 1$.

The weight $\alpha = (\alpha_{11}, \alpha_{12}, \cdots, \alpha_{1n}, \alpha_{22}, \cdots, \alpha_{2n}, \cdots, \alpha_{N-1, N})$ is an important parameter for the WSTNN. For the choice of the weight $\alpha$, we consider the following three cases.

**Case 1:** The tensor $N$-tubal rank of the underlying tensor is unknown and cannot be estimated empirically, such as the case of MRI data. Here, the weight $\alpha$ is chosen to be $\alpha = (1, 1, \ldots, 1)/N(N - 1)$.

**Case 2:** The tensor $N$-tubal rank of the underlying tensor $X \in \mathbb{R}^{n_1 \times n_2 \times \cdots \times n_N}$ is known, i.e.,

$$N - \text{rank}_k(X) = (r_{11}, r_{12}, \cdots, r_{1N}, r_{22}, \cdots, r_{2N}, \cdots, r_{N-1N}).$$

Since $z_{k_1 k_2}$ stands for the contribution of the TN of the mode-$k_1 k_2$ unfolding tensor $X_{(k_1, k_2)}$, the value of $z_{k_1 k_2}$ should be dependent on the tubal rank of $X_{(k_1, k_2)}$ ($r_{k_1 k_2}$) and the size of the first two modes of $X_{(k_1, k_2)}$ ($n_{k_1}$ and $n_{k_2}$). Specially, a larger (or smaller) ratio of $r_{k_1 k_2}$ to $\min(n_{k_1}, n_{k_2})$ corresponds to a smaller (or larger) value of $z_{k_1 k_2}$. Therefore, the following strategy is considered to choose the weight $\alpha$:

$$z_{k_1 k_2} = \frac{e^{r_{k_1 k_2}}}{\sum_{1 \leq k_1 < k_2 \leq N} e^{r_{k_1 k_2}}} \text{with} R = \sum_{1 \leq k_1 < k_2 \leq N} \tilde{r}_{k_1 k_2}, 1 \leq k_1 < k_2 \leq N, k_1, k_2 \in \mathbb{Z},$$

where $\tilde{r}_{k_1 k_2} = \min(n_{k_1}, n_{k_2})^{-r_{k_1 k_2}}$ and $\eta$ is a balance parameter.

---

$^2$ $\text{ones}(n, 1) \in \mathbb{R}^n$ is a vector whose elements are all 1.
Case 3: Particularly for HSI/MSI, although their exact $N$-tubal ranks are unknown, the correlations along their spectral modes should be much stronger than those along their spatial modes. This implies that the value of the first element of the $N$-tubal rank should be much larger than the values of its second and third elements. Thus, in this case, we empirically choose the weights $\alpha$ as $(\theta, 1, 1)/(2 + \theta)$, where $\theta$ is a balance parameter.

4. WSTNN-based models and solving algorithms

In this section, we apply the WSTNN to LRTC and TRPCA and propose the WSTNN-based models with ADMM-based solving schemes.

4.1. WSTNN-based LRTC model

Tensor completion aims at estimating the missing elements from an incomplete observation tensor. Considering an $N$-way tensor $\mathbf{X} \in \mathbb{R}^{n_1 \times n_2 \times \cdots \times n_N}$, the proposed WSTNN-based LRTC model is formulated as

$$\min_{\mathbf{X}} \|\mathbf{X}\|_{\text{WSTNN}}$$

s.t. $\mathcal{P}_\Omega(\mathbf{X} - \mathcal{F}) = 0,$

where $\mathbf{X}$ is the underlying tensor, $\mathcal{F}$ is the observed tensor, $\Omega$ is the index set for the known entries, and $\mathcal{P}_\Omega(\mathbf{X})$ is a projection operator that keeps the entries of $\mathbf{X}$ in $\Omega$ and sets all others to zero. Let

$$t_5(\mathbf{X}) := \begin{cases} 0, & \text{if } \mathbf{X} \in \mathbb{S}, \\ \infty, & \text{otherwise}, \end{cases}$$

where $\mathbb{S} := \{ \mathbf{X} \in \mathbb{R}^{n_1 \times n_2 \times \cdots \times n_N}, \mathcal{P}_\Omega(\mathbf{X} - \mathcal{F}) = 0 \}$. Then (12) can be rewritten as

$$\min_{\mathbf{X}} \sum_{1 \leq k_1 < k_2 \leq N} \alpha_{k_1 k_2} \|\mathbf{X}_{[k_1 k_2]}\|_{\text{TNN}} + t_5(\mathbf{X}),$$

where $\alpha_{k_1 k_2} \geq 0 (1 \leq k_1 < k_2 \leq N, k_1, k_2 \in \mathbb{Z})$ and $\sum_{1 \leq k_1 < k_2 \leq N} \alpha_{k_1 k_2} = 1.$

Algorithm 2 ADMM-based optimization algorithm for the proposed WSTNN-based LRTC model (12).

Input: The observed tensor $\mathcal{F}$, index set $\Omega$, weight $\alpha = (\alpha_{11}, \alpha_{12}, \cdots, \alpha_{1N}, \alpha_{21}, \cdots, \alpha_{2N}, \cdots, \alpha_{N-1N}), \beta = (\beta_{11}, \beta_{12}, \cdots, \beta_{1N}, \beta_{21}, \cdots, \beta_{2N}, \cdots, \beta_{N-1N}), \beta_{\text{max}} = (10^{10}, 10^{10}, \cdots, 10^{10}),$ and $\gamma = 1.1.$

Initialization: $\mathbf{X}^{(0)} = \mathcal{F}, \lambda_1^{(0)} = 0, \lambda_2^{(0)} = 0, \alpha_{k_1 k_2} = 0, p = 0, \text{and} \ p_{\text{max}} = 500.$

1: while not converged and $p < p_{\text{max}}$ do
2: Update $\mathcal{Y}_{k_1 k_2}^{(p+1)}$ via (19), $1 \leq k_1 < k_2 \leq N, k_1, k_2 \in \mathbb{Z}.$
3: Update $\mathbf{X}^{(p+1)}$ via (21),
4: Update $\lambda_1^{(p+1)}$ via (17), $1 \leq k_1 < k_2 \leq N, k_1, k_2 \in \mathbb{Z}.$
5: $\beta = \min(\gamma \beta, \beta_{\text{max}})$ and $p = p + 1.$
6: endwhile Output: The completed tensor $\mathbf{X}.$

Next, we use the ADMM to solve (14). We rewrite (14) as the following equivalent constrained problem

$$\min_{\mathbf{X}, \mathcal{Y}_{k_1 k_2}} \sum_{1 \leq k_1 < k_2 \leq N} \alpha_{k_1 k_2} \|\mathbf{Y}_{k_1 k_2}\|_{\text{TNN}} + t_5(\mathbf{X})$$

s.t. $\mathbf{X} - \mathcal{Y}_{k_1 k_2} = 0, \ 1 \leq k_1 < k_2 \leq N, k_1, k_2 \in \mathbb{Z}.$

The augmented Lagrangian function of (15) can be expressed in the following concise form

$$L_{\beta_{k_1 k_2}} (\mathbf{Y}_{k_1 k_2}, \mathbf{X}, \mathcal{M}_{k_1 k_2}) = \sum_{1 \leq k_1 < k_2 \leq N} \left\{ \alpha_{k_1 k_2} \|\mathbf{Y}_{k_1 k_2}\|_{\text{TNN}} + \frac{\beta_{k_1 k_2}}{2} \|\mathbf{X} - \mathbf{Y}_{k_1 k_2} + \mathcal{M}_{k_1 k_2}\|_F^2 \right\} + t_5(\mathbf{X}) + \mathcal{C},$$

where $\mathcal{M}_{k_1 k_2} (1 \leq k_1 < k_2 \leq N, k_1, k_2 \in \mathbb{Z})$ are Lagrange multipliers, $\beta_{k_1 k_2} (1 \leq k_1 < k_2 \leq N, k_1, k_2 \in \mathbb{Z})$ are penalty parameters, and $\mathcal{C}$ is a variable independent of $\mathbf{X}$ and $\mathbf{Y}_{k_1 k_2}.$ Within the framework of the ADMM, $\mathbf{Y}_{k_1 k_2}, \mathbf{X},$ and $\mathcal{M}_{k_1 k_2}$ are alternately updated as
The pseudocode of the developed algorithm is described in Algorithm 2.

We analyse the computational complexity of the developed algorithm, which involves three subproblems, i.e., the $Y_{k_1,k_2}$ subproblems, the $\mathcal{X}$ subproblem, and the $\mathcal{M}_{k_1,k_2}$ subproblems. Updating $Y_{k_1,k_2}$ requires performing SVD on $d_{k_1,k_2}$ matrices with a size of $(n_{k_1}, n_{k_2})$ and fast Fourier transformations (FFT) on $n_{k_1}$ vectors with a size of $d_{k_1}$, which cost $O(N \cdot \log(d_{k_1}) + N \cdot n_{k_1} + n_{k_2})$, where $D = \prod_{k_1=1}^N n_{k_1}$ and $d_{k_1,k_2} = D/(n_{k_1}n_{k_2})$. Updating $\mathcal{X}$ and $\mathcal{M}_{k_1,k_2}$ involves only scalar multiplication costing $O(D \sum_{1 \leq k_1 < k_2 \leq N} [\log(d_{k_1}) + \min(n_{k_1}, n_{k_2})])$. In summary, the computational cost at each iteration is $O(D \sum_{1 \leq k_1 < k_2 \leq N} [\log(d_{k_1}) + \min(n_{k_1}, n_{k_2})])$.

4.2. WSTNN-based TRPCA model

The TRPCA aims to exactly recover a low-rank tensor corrupted by sparse noise. Considering an $N$-way tensor $\mathcal{X} \in \mathbb{R}^{n_1 \times \cdots \times n_N}$, the proposed WSTNN-based TRPCA model can be formulated as

$$\min_{\mathcal{X}, \mathcal{L}} \left\| \mathcal{X} - \mathcal{L} \right\|_F^2 + \lambda \left\| \mathcal{L} \right\|_1$$

s.t. $\mathcal{X} = \mathcal{L} + \mathcal{E}$,
where $X$ is the corrupted observation tensor, $L$ is the low-rank component, $E$ is the sparse component, and $\lambda$ is a tuning parameter compromising $L$ and $E$. And (22) can be rewritten as

$$
\min_{L, E} \sum_{1 \leq k_1 < k_2 \leq N} a_{k_1 k_2} \|L_{k_1 k_2}\|_{TV} + \lambda \|E\|_1
$$

s.t. 

$$
X = L + E,
$$

where $a_{k_1 k_2} \geq 0$ (1 $\leq k_1 < k_2$ $\leq N, k_1, k_2 \in \mathbb{Z}$) and $\sum_{1 \leq k_1 < k_2 \leq N} a_{k_1 k_2} = 1$.

Next, we use the ADMM to solve (23). We rewrite (23) as

$$
\min_{L, E, Z_{k_1 k_2}} \sum_{1 \leq k_1 < k_2 \leq N} a_{k_1 k_2} \|\left(Z_{k_1 k_2}\right)_{(k_1 k_2)}\|_{TV} + \lambda \|E\|_1
$$

s.t. 

$$
X = L + E, \quad X - Z_{k_1 k_2} = 0, 1 \leq k_1 < k_2 \leq N, k_1, k_2 \in \mathbb{Z}.
$$

The augmented Lagrangian function of (24) can be expressed in the following concise form

$$
\min_{L, E, Z_{k_1 k_2}, \beta_{k_1 k_2}, \rho, \lambda, M} \sum_{1 \leq k_1 < k_2 \leq N} \left\{ a_{k_1 k_2} \|\left(Z_{k_1 k_2}\right)_{(k_1 k_2)}\|_{TV} + \frac{\lambda}{2} \|E\|_1^2 + \frac{\rho}{2} \|g\|_F^2 + \frac{M}{\rho} \|X - L - E\|_F^2 + C \right\}
$$

where $\beta_{k_1 k_2}$ and $M$ are Lagrange multipliers, $\beta_{k_1 k_2}$ and $\rho$ are penalty parameters, and $C$ is a variable independent of $L, E$, and $Z_{k_1 k_2}$. To minimize (25), we can update $L, Z_{k_1 k_2}, \beta_{k_1 k_2}, E, M (1 \leq k_1 < k_2 \leq N, k_1, k_2 \in \mathbb{Z})$ as

1. $Z_{k_1 k_2}^{(p+1)} = \text{arg min}_{Z_{k_1 k_2}} L_{k_1 k_2} \rho \left( \|L\|_{TV} + \|E\|_1 + \beta_{k_1 k_2} \|g\|_F^2 + \frac{M}{\rho} \|X - L - E\|_F^2 + C \right)$

2. $L_{k_1 k_2}^{(p+1)} = \text{arg min}_{L_{k_1 k_2}} \rho \left( \|L\|_{TV} + \|E\|_1 + \beta_{k_1 k_2} \|g\|_F^2 + \frac{M}{\rho} \|X - L - E\|_F^2 + C \right)$

3. $E^{(p+1)} = \text{arg min}_{E} \rho \left( \|L\|_{TV} + \|E\|_1 + \beta_{k_1 k_2} \|g\|_F^2 + \frac{M}{\rho} \|X - L - E\|_F^2 + C \right)$

4. $\beta_{k_1 k_2}^{(p+1)} = \beta_{k_1 k_2}^{(p)} + \rho \left( X - L^{(p+1)} - E^{(p+1)} \right)$

5. $M^{(p+1)} = M^{(p)} + \rho \left( X - L^{(p+1)} - E^{(p+1)} \right)$

In Step 1, the $Z_{k_1 k_2}$ (1 $\leq k_1 < k_2$ $\leq N, k_1, k_2 \in \mathbb{Z}$) subproblem can be solved as

$$
Z_{k_1 k_2}^{(p+1)} = \text{fold} \left( \left( L_{k_1 k_2}^{(p)} + \beta_{k_1 k_2}^{(p)} \left( X^{(0)} - L^{(0)} - E^{(0)} \right) \right) \right), 
$$

In Step 2, the $L$ subproblem has the following closed-form solution

Algorithm 3: ADMM-based optimization algorithm for the proposed WSTNN-based TRPCA model (22).

**Input:** The corrupted observation tensor $X$, weight $z = (x_{11}, x_{12}, \cdots, x_{1N}, x_{21}, \cdots, x_{2N}, \cdots, x_{N-1N})$.

- $\beta = (\beta_1, \beta_2, \cdots, \beta_{1N}, \beta_{21}, \cdots, \beta_{2N}, \cdots, \beta_{N-1N}), \beta_{\text{max}} = (10^{10}, 10^{10}, \cdots, 10^{10})$, $\lambda, \rho, p_{\text{max}} = 10^{10}$, and $\gamma = 1.2$.

1. **Initialization:** $L^{(0)} = 0, E^{(0)} = 0, M^{(0)} = 0, Z_{k_1 k_2}^{(0)} = 0, T_{k_1 k_2}^{(0)} = 0$, and $p_{\text{max}} = 500$.

2. **while** not converged and $p < p_{\text{max}}$

3. Update $Z_{k_1 k_2}^{(p+1)}$ via (27), 1 $\leq k_1 < k_2$ $\leq N$.

4. Update $L^{(p+1)}$ via (28).

5. Update $E^{(p+1)}$ via (30).

6. Update $T_{k_1 k_2}^{(p+1)}$ via (26), 1 $\leq k_1 < k_2$ $\leq N$.

7. Update $M^{(p+1)}$ via (26).

8. $\beta = \min(\gamma \beta, \beta_{\text{max}})$, $\rho = \min(\gamma \rho, p_{\text{max}})$, and $p = p + 1$.

9. **endwhile**

**Output:** The low-rank component $L$ and the sparse component $E$. 
In Step 3, we solve the following problem
\[
E^{(p+1)} = \arg \min_{g} \kappa \|X - X^{(p)} - E^{(p)}\|_F + \frac{D}{2} \|X - L^{(p+1)} - E + \frac{M^{(p)}}{\rho} g\|^2_F,
\]
which has the following closed-form solution
\[
E^{(p+1)} = \mathcal{S}_\kappa (X - L^{(p+1)} + \frac{M^{(p)}}{\rho}),
\]
where \(\mathcal{S}_\kappa (\cdot)\) is the tensor soft thresholding operator with threshold \(\kappa\), i.e.,
\[
[\mathcal{S}_\kappa (X)]_{i_1 \ldots i_k} = \max(|x_{i_1 \ldots i_k}| - \kappa, 0).
\]

The pseudocode of the proposed algorithm for solving the proposed WSTNN-based TRPCA model (22) is described in Algorithm 3.

We analyse the detailed computational complexity of the developed algorithm, which involves five subproblems, i.e., the \(Z_{k_1k_2}\) subproblem, the \(L\) subproblem, the \(E\) subproblem, the \(P_{k_1k_2}\) subproblem, and the \(M\) subproblems. Updating \(Z_{k_1k_2}\) requires performing SVD on \(d_{k_1k_2}\) matrices with a size of \((n_{k_1}, n_{k_2})\) and FFT on \(n_{k_1}n_{k_2}\) vectors with a size of \(d_{k_1k_2}\), which cost \(O(D \log (d_{k_1k_2}) + \min(n_{k_1}, n_{k_2}))\) where \(D = \prod_{k_1, k_2} n_{k_1}d_{k_1k_2}\). Updating \(L\), \(E\), \(P_{k_1k_2}\), and \(M\) involves only scalar multiplication costing \(O(D\sum_{1 \leq k_1 < k_2} \log (d_{k_1k_2}) + \min(n_{k_1}, n_{k_2}))\).

5. Numerical experiments

We evaluate the performance of the proposed WSTNN-based LRTC and TRPCA methods. Both synthetic and real-world data are tested. We employ the peak signal-to-noise rate (PSNR), the structural similarity (SSIM) [33], and the feature similarity (FSIM) [41] to measure the quality of the recovered results. All tests are implemented on the Windows 7 platform and MATLAB (R2017b) with an Intel Core i5-4590 3.30 GHz and 16 GB of RAM.

5.1. Low-rank tensor completion

In this section, we test synthetic data and five kinds of real-world data: MSI, HSI, MRI, color video (CV), and hyperspectral video (HSV). If not specified, the methodology for sampling the data is purely random sampling. The compared LRTC methods are as follows: HaLRTC [24] and LRTC-TVI [23], representing the state of the art for the Tucker-decomposition-based method; BCPF [44], representing the state of the art for the CP-decomposition-based method; and logDet [14], TNN [43], PSTNN [16], and t-TNN [12], representing the state of the art for the t-SVD-based method. Because logDet, the TNN, the PSTNN, and the t-TNN apply only to three-way tensors, in all four-way tensor tests, we first reshape the four-way tensors into three-way tensors and then test the performances of these methods.

Parameter selection. In all tests, the stopping criterion depends on the relative change (RelCha) in two successive recovered tensors, i.e., RelCha = \(\frac{\|X^{(p+1)} - X^{(p)}\|_F}{\|X^{(p)}\|_F}\) < 10^{-4}. Letting the threshold parameter \(\tau = \alpha/\beta\), \(\alpha\) is chosen by the weight selection strategy presented in Section 3, \(\tau\) is set to \(\omega \times \text{ones}(N(N-1)/2, 1)\), where \(\omega\) is empirically selected from a candidate set: \([1, 10, 50, 100, 500, 1000, 10000]\). Table 2 shows the parameter settings for the proposed WSTNN-based LRTC method on different data.

Synthetic data completion. We test both synthetic three-way tensors of size 30 × 30 × 30 and four-way tensors of size 30 × 30 × 30 × 30. The tested synthetic tensors consist of the sum of \(r\) rank-one tensors, which are generated by finding the vector outer product on \(N (N = 3)\) random vectors. In practice, the data in each test are regenerated and confirmed to meet the conditions of Theorem 3, i.e., the \(N\)-tubal rank is \(r \times \text{ones}(N (N - 1)/2, 1)\). We define the success rate as the ratio of successful times to the total number of times, where one test is successful if the relative square error of the recovered tensor \(\hat{X}\) and the ground-truth tensor \(X\), i.e., \(\|\hat{X} - X\|_F^2/\|X\|_F^2\), is less than 10^{-3}.

We test data with different \(N\)-tubal ranks and sampling rates (SRs), which is defined as the proportion of the known elements. The \(N\)-tubal ranks are set to \(r \times \text{ones}(N (N - 1)/2, 1)\), and the SRs are set to 0.05 × \(s = 1, 2, \ldots, 19\). For each \(N\)-tubal rank and SR pair, we conduct 50 independent tests and calculate the success rate. Fig. 3 shows the success.

Footnote: The codes of the WSTNN-based LRTC and TRPCA methods are available at https://yubangzheng.github.io/.
rates for various N-tubal ranks and SRs. It is obvious that under a varying N-tubal rank, the proposed WSTNN-based LRTC method requires less sampling than the TNN-based method\cite{43} to successfully recover the target tensor.

**MRI completion.** We test an MRI\cite{5} data set of size $181 \times 217 \times 181$. Table 4 lists the values of the PSNR, SSIM, and FSIM of the tested MRI recovered by the different LRTC methods. As observed, the proposed method significantly outperforms the compared methods in terms of all evaluation indices. In Fig. 5, we show three slices obtained in different directions. It can be observed that no matter which direction they are in, the proposed method is evidently superior to the compared ones in the recovery of both abundant shape structure and texture information. The HSI completion results can be found in the Appendix.

**CV completion.** We test the CV news\cite{6} of size $144 \times 176 \times 3 \times 50$. For each frame, the missing elements of each channel have the same location. Table 5 lists the values of the PSNR, SSIM, and FSIM of the tested CV recovered by different LRTC methods. As

---

**Fig. 3.** The success rates for synthetic data with a varying N-tubal rank and varying SR. The left two are the results of the TNN-based LRTC method\cite{43} and the proposed WSTNN-based LRTC method on three-way tensors. The right two are the results of the TNN-based LRTC method\cite{43} and the proposed WSTNN-based LRTC method on four-way tensors. The gray magnitude represents the success rates.
observed, the proposed method has an overall better performance than that of the compared ones with respect to all evaluation indices. In Fig. 6, we show one frame in the tested CV recovered by the eight compared methods with SR = 10%. We observe that the results obtained by the proposed method are superior to those obtained by the compared ones.

HSV completion. We test an HSV\(^7\) of size \(120 \times 120 \times 33 \times 31\). Specifically, this HSV has 31 frames, and each frame has 33 bands of wavelengths of from 400 nm to 720 nm with a 10 nm step [27]. Table 6 lists the values of the PSNR, SSIM, and FSIM of the tested HSV recovered by different LRTC methods. As observed, the proposed method consistently achieves the highest values in terms of all evaluation indexes, e.g., no matter what the SR is set to, the proposed method achieves an approximately 4 dB gain in the PSNR compared with the second-best method. In Fig. 7, we show two images located at different frames and different bands in the HSV recovered by the eight compared methods with SR = 5%. We observe that the proposed method is evidently superior to the compared ones, especially in the recovery of texture information.

\(^7\) http://openremotesensing.net/knowledgebase/hyperspectral-video/.
we observe that our method evidently performs better than the other competing ones in terms of all the evaluation measures. The PSNR, SSIM, and FSIM values output by the eight utilized LRTC methods for CVs.

5.2. Tensor robust principal component analysis

In this section, we evaluate the performance of the proposed WSTNN-based TRPCA method by synthetic data and HSI denoising. The compared TRPCA methods include the SNN [9] and TNN [25].

**Parameter selection.** In all tests, the stopping criterion depends on the RelCha in two successive recovered tensors, i.e.,

\[
\text{RelCha} = \frac{\| C_{(k+1)} - C_k \|_F}{\| C_k \|_F} < 10^{-4}.
\]

The tuning parameter \( \lambda \) is set to

\[
\lambda = \sum_{1 \leq k_1 < k_2 \leq N} \frac{\alpha_{k_1 k_2}}{\max(n_{k_1}, n_{k_2})} \text{with } d_{k_1 k_2} = \prod_{s \neq k_1 k_2} n_s.
\]

Letting the threshold parameter \( \tau = \alpha / \beta \), the penalty parameter \( \rho \) is set to \( \rho = 1 / \text{mean}(\tau) \). This means that only the weight \( \alpha \) and the threshold \( \tau \) need to be adjusted. Table 7 shows these two parameter settings for the proposed WSTNN-based TRPCA method on different data, where \( \alpha \) is chosen by the weight selection strategy presented in Section 3, \( \tau \) is set to \( \omega \times \text{ones}(N(N-1)/2, 1) \), and \( \omega \) is empirically selected from a candidate set: \{1, 10, 50, 100, 500, 1000, 10000\}.

**Synthetic data denoising.** We test three-way tensors of size \( 30 \times 30 \times 30 \) and four-way tensors of size \( 30 \times 30 \times 30 \times 30 \) with different N-tubal ranks and random salt-pepper noise levels (NLs). The N-tubal ranks are set to \( r \times \text{ones}(N(N-1)/2, 1) \) \((r = 1, 2, \ldots, 20) \), and the NLs are set to 0.025 \( x l(l = 1, 2, \ldots, 20) \). For each N-tubal rank and NL pair, we conduct 50 independent tests and calculate the success rate. Fig. 8 shows the success rates for varying N-tubal rank and varying NL. The results illustrate that the proposed WSTNN-based TRPCA method is more robust and preferable than the TNN-based method [25].

**HSI denoising.** We test the *Washington DC Mall* and *Pavia University* HSI data sets. The random salt-pepper NL is set to 0.2 and 0.4. Table 8 lists the PSNR, SSIM, and FSIM values of the tested HSIs recovered by different methods. From these results, we observe that our method evidently performs better than the other competing ones in terms of all the evaluation mea-
In Fig. 9, we show one band in these two HSIs. As observed, our WSTNN-based TRPCA method achieves the best visual results among those of the three compared methods in terms of both noise removal and detail preservation.

5.3. Parameter study and convergence analysis

In this section, we discuss the effects of the threshold parameter $\tau$ and the convergence of the proposed ADMM in the proposed LRTC and TRPCA problems. All tests are based on the HSI Washington DC Mall.

**Effects of the threshold parameter.** We set the SR to 10% in the completion tests and the NL to 0.4 in the denoising tests. In addition, $\tau = (\alpha, \omega, \alpha)$. The results are presented in Fig. 10(a). As observed, values of $\tau$ that are too large or too small result in failure, while moderate values yield the best results. This observation is consistent with the theoretical analysis. That is,
for the completion tests, if \( s \) is too large (e.g., 10000; 10000; 10000), all the singular values are replaced with 0, and the algorithm iterates only one step and outputs the partial observation tensor \( F \). If the parameter \( s \) is too small (e.g., 10; 10; 10), the singular values obtained after performing the t-SVT (in Theorem 4) contain corrupted information, which is not consistent with the low-rank prior of the underlying tensor. Similarly, for the denoising tests, if the parameter \( s \) is too large or too small, the low-rank term becomes out of action. Under the guidance of Fig. 10(a), \( s \) is set to 100; 100; 100 in all experiments conducted on real-world data.

**Convergence analysis.** Owing to the use of the ADMM framework and the convexity of the objective functions, the convergence of the two developed algorithms is guaranteed theoretically. Empirically, this convergence can be visually observed in Fig. 10(b), where \( s \) is set to (100, 100, 100). For future work, there are three directions. First, the mechanism of all low-rank models lies in the assumption that the original data has a stronger low-rankness than the observed one. Therefore, the proposed method tends to fail when the observed data have the same, or even stronger, low-N-tubal-rank property compared with the original one. One challenging example is the missing slice problem, which usually results in observed data with a lower N-tubal rank than that of the original data. To solve this issue and further improve the completion performance, we plan to combine the proposed global low-N-tubal-rankness prior to some other priors, such as the piecewise smoothness prior, nonlocal self-similarity prior, and deep prior. Second, we plan to establish some nonconvex relaxations [39,40,42] to further improve the performance of the proposed method. Third, for MSIs/HSIs, we plan to combine the proposed WSTNN with the recent excellent MSI/HSI processing methods, such as FastHyDe [49] and NG-meet [10], to enhance the ability to recover the target HSI.
Acknowledgments

The authors would like to express their sincere thanks to the reviewers for their helpful suggestions regarding how to revise this paper. It is their dedication and sacrifice that provide people a secure and stable research environment in this special time.

Appendix A

1. Examples of Definition 5.

For a four-way tensor \( X \in \mathbb{R}^{2 \times 3 \times 2 \times 3} \), its \((i_2,i_4)\)-th mode-13 slice and \((i_1, i_3)\)-th mode-24 slice are

\[
X^{13} = \begin{pmatrix}
X(1, i_2, 1, i_4) & X(1, i_2, 2, i_4) & X(1, i_2, 3, i_4) \\
X(2, i_2, 1, i_4) & X(2, i_2, 2, i_4) & X(2, i_2, 3, i_4)
\end{pmatrix}
\]

and

\[
X^{24} = \begin{pmatrix}
X(i_1, 1, i_3, 1) & X(i_1, 1, i_3, 2) \\
X(i_1, 2, i_3, 1) & X(i_1, 2, i_3, 2)
\end{pmatrix},
\]

respectively.

2. Examples of Definition 6.

For a four-way tensor \( X \in \mathbb{R}^{2 \times 3 \times 2 \times 3} \), its mode-24 unfolding tensor \( X_{(24)} \in \mathbb{R}^{2 \times 2 \times 6} \) can be expressed as

\[
X_{(24); :, 1} = \begin{pmatrix}
X(1, 1, 1, 1) & X(1, 1, 1, 2) \\
X(1, 2, 1, 1) & X(1, 2, 1, 2)
\end{pmatrix},
\]

\[
X_{(24); :, 2} = \begin{pmatrix}
X(2, 1, 1, 1) & X(2, 1, 1, 2) \\
X(2, 2, 1, 1) & X(2, 2, 1, 2)
\end{pmatrix},
\]

\[
X_{(24); :, 3} = \begin{pmatrix}
X(3, 1, 1, 1) & X(3, 1, 1, 2) \\
X(3, 2, 1, 1) & X(3, 2, 1, 2)
\end{pmatrix},
\]

\[
X_{(24); :, 4} = \begin{pmatrix}
X(1, 1, 2, 1) & X(1, 1, 2, 2) \\
X(1, 2, 2, 1) & X(1, 2, 2, 2)
\end{pmatrix},
\]

\[
X_{(24); :, 5} = \begin{pmatrix}
X(2, 1, 2, 1) & X(2, 1, 2, 2) \\
X(2, 2, 2, 1) & X(2, 2, 2, 2)
\end{pmatrix},
\]

\[
X_{(24); :, 6} = \begin{pmatrix}
X(3, 1, 2, 1) & X(3, 1, 2, 2) \\
X(3, 2, 2, 1) & X(3, 2, 2, 2)
\end{pmatrix}.
\]

3. Proof of Theorem 2. (N-tubal rank and Tucker rank)

Proof. Apparently, the mode-\( k_1 \times k_2 \) unfolding tensor of \( X \) can be expressed as

\[
X_{(k_1 \times k_2)} = \sum_{i_1=1}^{n_1} \sum_{i_2=1}^{n_2} a_{i_1}^{k_1} \circ a_{i_2}^{k_2} \circ c_{i_1,i_2},
\]

where \( c_{i_1,i_2} = v \in C_{i_1,i_2} \) with

Fig. 11. The completion results of the HSIs Washington DC Mall and Pavia University with SR = 5%. Top row: the image located at the 70-th band in Washington DC Mall. Bottom row: the image located at the 85-th band in Pavia University.

4. Proof of Theorem 3 (N-tubal rank and CP rank).

Proof. The $X^{(k_1 k_2)}$ has the following CP decomposition

$$X^{(k_1 k_2)} = \sum_{i=1}^{r} a_{k_1}^{i} \circ a_{k_2}^{i} \circ c_{i}.$$
Letting $\tilde{\lambda}(k_1, k_2) = \mathcal{F}(\lambda(k_1, k_2))$, then $\tilde{\lambda}(k_1, k_2)$ has the following CP decomposition

$$\lambda(k_1, k_2) = \sum_{i=1}^{n} \mathbf{a}_i \circ \mathbf{a}_i \circ \mathbf{c}_i,$$

where $\mathbf{c}_i = \mathcal{F}(\mathbf{c}_i)$. Letting $\mathbf{c}_i = (c_{i1}, c_{i2}, \ldots, c_{iN})$, then the $j$-th frontal slice of $\lambda(k_1, k_2)$ can be expressed as

$$\lambda^{(j)}(k_1, k_2) = \mathbf{c}_1^j \mathbf{a}_1^j + \mathbf{c}_2^j \mathbf{a}_2^j + \cdots + \mathbf{c}_N^j \mathbf{a}_N^j.$$

This implies that the rank of each frontal slice of $\lambda(k_1, k_2)$ is at most $r$, and it is equal to $r$ if the vector sets $\mathbf{v}_1$ or $\mathbf{v}_2$ is linearly independent and the $j$-th element of each $\mathbf{c}_i$ is non-zero. Thus, the tubal rank of $\lambda(k_1, k_2)$ (the $(k_1, k_2)$-th element of the $N$-tubal rank of $\lambda$) is at most $r$, and it is equal to $r$ if the aforementioned conditions are satisfied.

## 5. HSI completion.

We test HSIs *Washington DC Mall* and *Pavia University*. Table 9 lists the values of the PSNR, SSIM, and FSIM of these two tested HSIs recovered by different LRTC methods. We observe that compared with other methods, the proposed method consistently achieves the highest values in terms of all evaluation indexes, e.g., when SR is set as 5% or 10%, the proposed method achieves around 7 dB gain in PSNR beyond the second-best method in the test on *Washington DC Mall*. For visual comparison, in Fig. 11, we show one band in these two testing HSIs recovered by the eight utilized LRTC methods with SR = 5%. As observed, the proposed method can produce visually superior results than the compared methods. Fig. 12 shows the PSNR, SSIM and FSIM values of each band of the recovered HSI *Washington DC Mall* obtained by the eight compared LRTC methods with SR = 5%. From this figure, it is easy to observe that the proposed method achieves the best performance in all bands among eight LRTC methods.
